

# FOUNDATION

# Pure function

# Functions with side effects are not pure

# Functional programming is useless \*

[Simon Peyton Jones](#) co-author of haskell

A pure function cannot do anything  
it can only produce a value

Create a value that describes actions

Create a value that describes actions

Interpret this value in Main

## 1. Encode description of actions

```
trait Description[A]
```

## 2. Define an interpreter of Description

```
def unsafeRun[A](fa: Description[A]): A = ???
```

## 3. Combine everything in Main

```
object Main extends App {  
  val description: Description[Unit] = ???  
  unsafeRun(description)  
}
```

# Run side effects at the edges

# Examples of description / evaluation

# Cooking

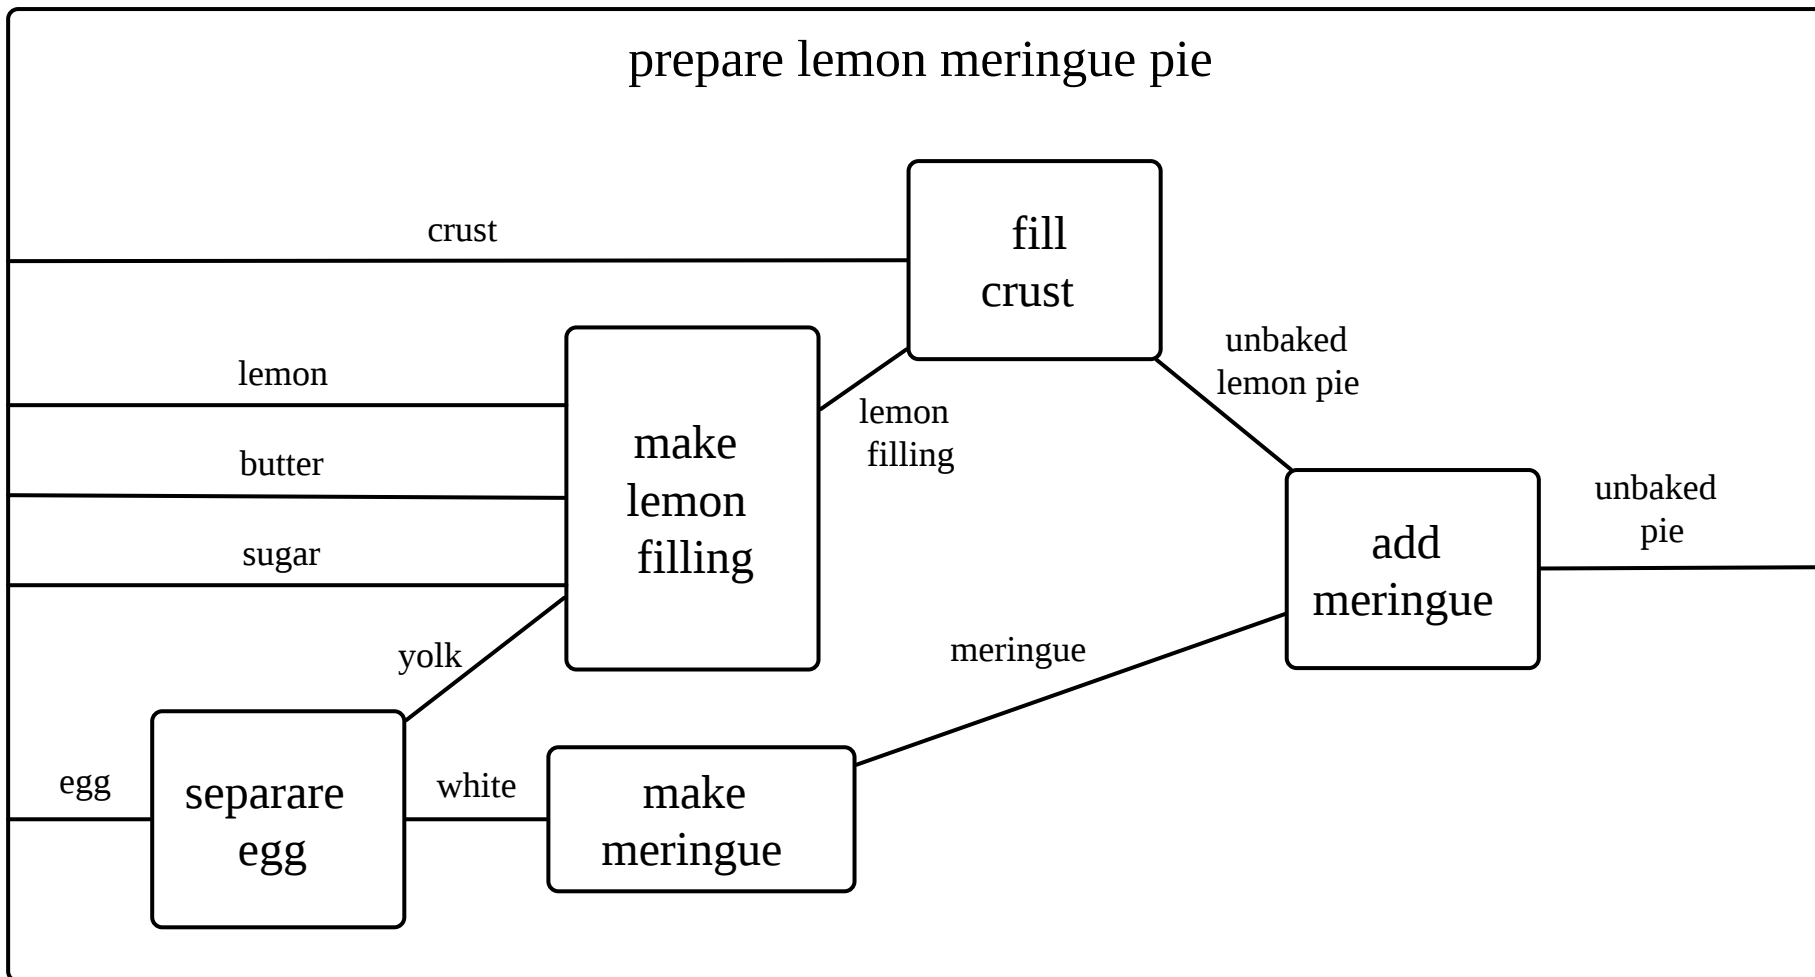

## 1. Secret pasta recipe (Description)

1. Boil 200 ml of water
2. Add 250 g of dry pasta
3. Wait 11 minutes
4. Drain the pasta

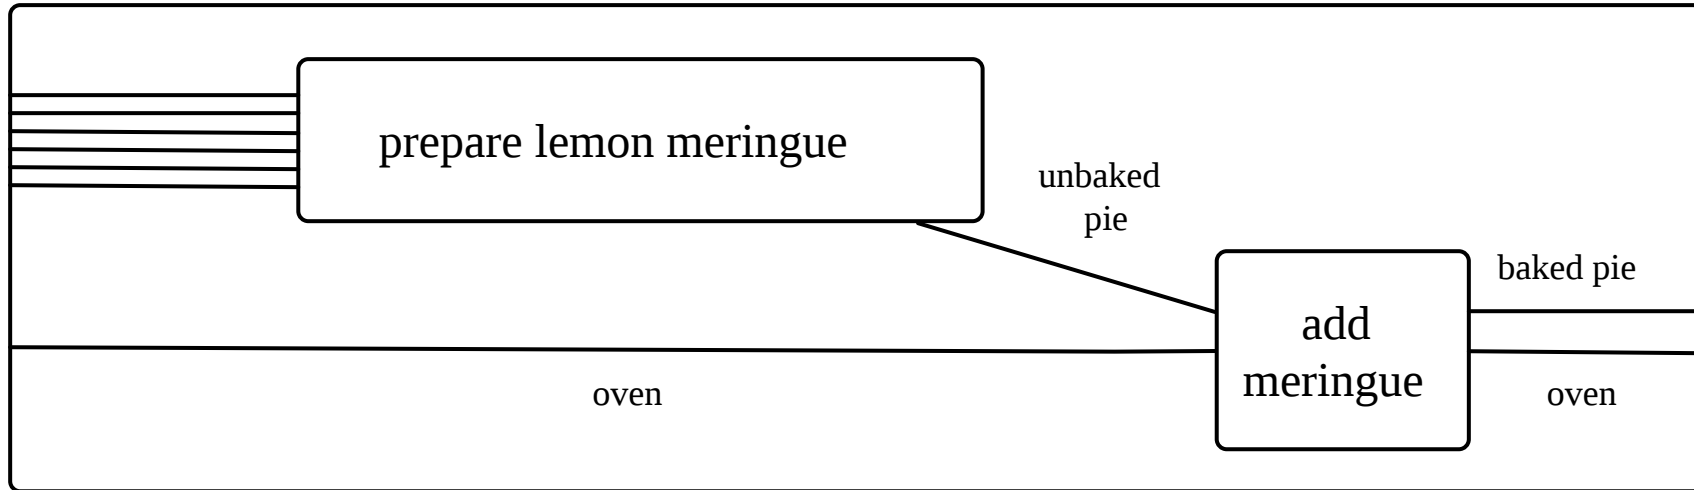

## 2. Cook (Unsafe evaluation)

Take the recipe and do it at home

# String diagrams compose

# Mathematical formula

```
val x = 2
// x: Int = 2
val y = 3
// y: Int = 3
val x2 = Math.pow(x, 2)
// x2: Double = 4.0
val y2 = Math.pow(y, 2)
// y2: Double = 9.0
val z = Math.sqrt(x2 + y2)
// z: Double = 3.605551275463989
```

# Mathematical formula

```
val x2 = Math.pow(x, 2)
// x2: Double = 4.0
val y2 = Math.pow(y, 2)
// y2: Double = 9.0
val z = Math.sqrt(x2 + y2)
// z: Double = 3.605551275463989

Math.pow(z, 2)
// res1: Double = 12.999999999999998
x2 + y2
// res2: Double = 13.0
```

# How to encode description?

```
trait Description[A]  
  
def unsafeRun[A](fa: Description[A]): A = ???
```

# Thunk

```
type Thunk[A] = () => A // Unit => A

def writeLine(message: String): Thunk[Unit] =
  () => println(message)

val today: Thunk[LocalDate] =
  () => LocalDate.now()

def fetch(url: String): Thunk[Iterator[String]] =
  () => scala.io.Source.fromURL(url)("ISO-8859-1").getLines
```

# Thunk

```
type Thunk[A] = () => A // Unit => A

def writeLine(message: String): Thunk[Unit] =
  () => println(message)

val today: Thunk[LocalDate] =
  () => LocalDate.now()

def fetch(url: String): Thunk[Iterator[String]] =
  () => scala.io.Source.fromURL(url)("ISO-8859-1").getLines
```

```
def unsafeRun[A](fa: Thunk[A]): A = fa()
```

# Thunk

```
type Thunk[A] = () => A // Unit => A

def writeLine(message: String): Thunk[Unit] =
  () => println(message)

val today: Thunk[LocalDate] =
  () => LocalDate.now()

def fetch(url: String): Thunk[Iterator[String]] =
  () => scala.io.Source.fromURL(url)("ISO-8859-1").getLines
```

```
def unsafeRun[A](fa: Thunk[A]): A = fa()
```

```
val google = fetch("http://google.com")
// google: () => Iterator[String] = <function0>
unsafeRun(google).take(1).toList
// res3: List[String] = List(
//   "<!doctype html><html itemscope=\"\" itemtype=\"http://schema.org/WebPage\" lang=\"en\"><head><meta content=\"S
```

# IO

```
trait IO[A] {  
  def unsafeRun(): A // unique abstract method  
  
  def map[B](f: A => B): IO[B] = ???  
  def flatMap[B](f: A => IO[B]): IO[B] = ???  
  def retry: IO[A] = ???  
}
```

# IO

```
trait IO[A] {  
  def unsafeRun(): A // unique abstract method  
  
  def map[B](f: A => B): IO[B] = ???  
  def flatMap[B](f: A => IO[B]): IO[B] = ???  
  def retry: IO[A] = ???  
}
```

```
def writeLine(message: String): IO[Unit] =  
  new IO[Unit] {  
    def unsafeRun(): Unit = println(message)  
  }
```

```
val helloWorld = writeLine("Hello World")  
// helloWorld: IO[Unit] = repl.Session$App4$$anon$1@19eea716  
  
helloWorld.unsafeRun()  
// Hello World
```

# Implement our own IO

# Smart constructors

```
object IO {  
  def succeed[A](constant: A): IO[A] = ???  
  def effect[A](block: => A): IO[A] = ???  
  def fail[A](error: Throwable): IO[A] = ???  
}  
  
trait IO[A] {  
  def unsafeRun(): A  
}
```

# IO Exercises

`exercises.sideeffect.IOExercises.scala`

# IO Summary

- An IO is a thunk of potentially impure code
- Composing IO is referentially transparent, nothing get executed
- It is easier to test IO if they are defined in a interface

# I/O Execution

# IO execution

```
case class UserId (value: String)
case class OrderId(value: String)

case class User(userId: UserId, name: String, orderIds: List[OrderId])
```

```
def getUser(userId: UserId): IO[User] =
  IO.effect{
    val response = httpClient.get(s"http://foo.com/user/${userId.value}")
    if(response.status == 200) parseJson[User](response.body)
    else throw new Exception(s"Invalid status ${response.status}")
  }

def deleteOrder(orderId: OrderId): IO[Unit] =
  IO.effect{
    val response = httpClient.delete(s"http://foo.com/order/${orderId.value}")
    if(response.status == 200) () else throw new Exception(s"Invalid status ${response.status}")
  }
```

# How is it executed?

```
def deleteAllUserOrders(userId: UserId): IO[Unit] =  
  for {  
    user <- getUser(userId)  
    _ <- traverse(user.orderIds)(deleteOrder)  
  } yield ()  
  
object Main extends App {  
  deleteAllUserOrders(UserId("1234")).unsafeRun()  
}
```

Discuss with your neighbour 3-4 min

# How is it executed?

```

# IO Async Exercises

`exercises.sideeffect.IOAsyncExercises.scala`

# Libraries do much more

- Stack safety and JVM optimisation
- Cancellation, e.g. race two IO and cancel the loser
- Safe resource shutdown, e.g. close file, shutdown server
- Efficient Timer, retry utilities
- Help to chose right thread pool for different type of work: blocking, compute, dispatcher
